Superheated steam is a steam at a temperature higher than its vaporization (boiling) point at the absolute pressure where the temperature is measured.. The steam can therefore cool (lose internal energy) by some amount, resulting in a lowering of its temperature without changing state (i.e., condensing) from a gas, to a mixture of saturated vapor and liquid.

What is superheated steam? When water molecules exist in a gaseous-state at a temperature above the boiling temperature of water, it is called the superheated steam-state. The boiling temperature depends on the pressure (e.g. 100 °C for 1 atmosphere, or 134 °C for 3 atmosphere and so on). When only at the boiling-temperature, the steam is called saturated steam.

Steam is water in the gas phase, which is formed when water boils. Steam is invisible; however, "steam" often refers to wet steam, the visible mist or aerosol of water droplets formed as this water vapour condenses. At lower pressures, such as in the upper atmosphere or at the top of high mountains, water boils at a lower temperature than the nominal 100 °C (212 °F) at standard pressure.

Generating Steam and Steam Quality. Steam is the autoclave's sterilization agent. In our Sterilization Methods series, we explained the physics of steam and why it's ideal for destroying microorganisms such as bacteria and spores. Part 1 of this post will explain how steam is generated for autoclaving purposes.

\* Two common measures of energy are British thermal units (Btu) and joules. All forms of energy can be expressed in these units. One Btu is the amount of energy needed to raise the temperature of one pound of water from 39 to 40 degrees Fahrenheit. One joule is the amount of energy needed to lift one hundred grams (3.5 ounces) upward by one meter (3.3 feet) while on the surface of the earth.
